# 1. Counting missing values

Sports clothing and athleisure attire is a huge industry, worth approximately \$193 billion in 2021 with a strong growth forecast over the next decade!

In this notebook, we play the role of a product analyst for an online sports clothing company. The company is specifically interested in how it can improve revenue. We will dive into product data such as pricing, reviews, descriptions, and ratings, as well as revenue and website traffic, to produce recommendations for its marketing and sales teams.

The database provided to us, sports, contains five tables, with product\_id being the primary key for all of them:

#### info

column	data type	description
<pre>product_name</pre>	varchar	Name of the product
product_id	varchar	Unique ID for product
description	varchar	Description of the product

## finance

column	data type	description
<pre>product_id</pre>	varchar	Unique ID for product
listing_price	float	Listing price for product
sale_price	float	Price of the product when on sale
discount	float	Discount, as a decimal, applied to the sale price
revenue	float	Amount of revenue generated by each product, in US dollars

### reviews

column	data type	description
<pre>product_name</pre>	varchar	Name of the product
product_id	varchar	Unique ID for product
rating	float	Product rating, scored from 1.0 to 5.0
reviews	float	Number of reviews for the product

#### traffic

column	data type	description
<pre>product_id</pre>	varchar	Unique ID for product
last_visited	timestamp	Date and time the product was last viewed on the website

#### brands

column	data type	description
<pre>product_id</pre>	varchar	Unique ID for product
brand	varchar	Brand of the product

We will be dealing with missing data as well as numeric, string, and timestamp data types to draw insights about the products in the online store. Let's start by finding out how complete the data is.

1 rows affected.

#### Out[93]: total\_rows count\_description count\_listing\_price count\_last\_visited

3179 3117 3120 2928

```
def test_values():
    assert last_output_df.values.tolist() == [[3179, 3117, 3120, 2928]], \
    """Did you correctly calculate the values for each column? Expected different results.
```

Out[94]: 3/3 tests passed

# 2. Nike vs Adidas pricing

We can see the database contains 3,179 products in total. Of the columns we previewed, only one — last\_visited — is missing more than five percent of its values. Now let's turn our attention to pricing.

How do the price points of Nike and Adidas products differ? Answering this question can help us build a picture of the company's stock range and customer market. We will run a query to produce a distribution of the listing\_price and the count for each price, grouped by brand.

## 3. Labeling price ranges

It turns out there are 77 unique prices for the products in our database, which makes the output of our last query quite difficult to analyze.

Let's build on our previous query by assigning labels to different price ranges, grouping by brand and label. We will also include the total revenue for each price range and brand.

```
ON finance.product id = brands.product id
          WHERE brand IS NOT NULL
          GROUP BY brand, price_category
          ORDER BY total_revenue DESC;
          8 rows affected.
Out[97]: brand count

# 4. Average discount by brand

['Nike', 16, 6623.5, 'Average']], \

Interestingly, grouping products by brand and price range allows us to see that Adidas items generate more total revenue regardless of price category! Specifically, "Elite" Adidas products priced \$129 or more typically generate the highest revenue, so the company can

"Did you correctly calculate values for Nike products? Expected something differer

potentially increase revenue by shifting their stock to have a larger proportion of these products!

Note we have been looking at listing\_price so far. The listing\_price may not be the price that the product is ultimately sold for. To understand revenue better, let's take a look at the discount, which is the percent reduction in the listing\_price when the product is actually sold. We would like to know whether there is a difference in the amount of discount offered between brands, as this could be influencing revenue.

```
In [99]:
         %%sql
          SELECT brand, AVG(discount) * 100 AS average discount
          FROM finance
          INNER JOIN brands
              ON finance.product_id = brands.product_id
          GROUP BY brand
          HAVING brand IS NOT NULL;

```

Out[100]: 3/3 tests passed

### 5. Correlation between revenue and reviews

Strangely, no discount is offered on Nike products! In comparison, not only do Adidas products generate the most revenue, but these products are also heavily discounted!

To improve revenue further, the company could try to reduce the amount of discount offered on Adidas products, and monitor sales volume to see if it remains stable. Alternatively, it could try offering a small discount on Nike products. This would reduce average revenue for these products, but may increase revenue overall if there is an increase in the volume of Nike products sold.

Now explore whether relationships exist between the columns in our database. We will check the strength and direction of a correlation between revenue and reviews .

```
In [101...
         %%sql
          SELECT CORR(reviews, revenue) AS review revenue corr
           FROM finance
          INNER JOIN reviews
              ON finance.product_id = reviews.product_id;

               "Did you calculate the correlation between reviews and revenue?"
           def test values():
              assert last_output_df.values.tolist() == [[0.6518512283481301]], \
               "Did you correctly calculate how reviews correlates with revenue?"
```

Out[102]: 3/3 tests passed

# 6. Ratings and reviews by product description length

Interestingly, there is a strong positive correlation between revenue and reviews . This means, potentially, if we can get more reviews on the company's website, it may increase sales of those items with a larger number of reviews.

Perhaps the length of a product's description might influence a product's rating and reviews — if so, the company can produce content guidelines for listing products on their website and test if this influences revenue. Let's check this out!

## 7. Reviews by month and brand

Unfortunately, there doesn't appear to be a clear pattern between the length of a product's description and its rating.

As we know a correlation exists between reviews and revenue, one approach the company could take is to run experiments with different sales processes encouraging more reviews from customers about their purchases, such as by offering a small discount on future purchases.

Let's take a look at the volume of reviews by month to see if there are any trends or gaps we can look to exploit.

<sup>\*</sup> postgresql:///sports

## 8. Footwear product performance

Looks like product reviews are highest in the first quarter of the calendar year, so there is scope to run experiments aiming to increase the volume of reviews in the other nine months!

So far, we have been primarily analyzing Adidas vs Nike products. Now, let's switch our attention to the type of products being sold. As there are no labels for product type, we will create a Common Table Expression (CTE) that filters description for keywords, then use the results to find out how much of the company's stock consists of footwear products and the median revenue generated by these items.

1 rows affected.

Out[107]: num\_footwear\_products median\_footwear\_revenue

2700 3118.36

```
assert last_output_df.shape[1] == 2, \
    "Expected the output to contain two columns."

    "Did you count the number of footwear products?"
    assert last_output_df.iloc[0,1] == 3118.36, \
    "Did you calculate the median revenue for footwear products?"
```

Out[108]: 3/3 tests passed

def test columns():

# 9. Clothing product performance

Recall from the first task that we found there are 3,117 products without missing values for description. Of those, 2,700 are footwear products, which accounts for around 85% of the company's stock. They also generate a median revenue of over \$3000 dollars!

This is interesting, but we have no point of reference for whether footwear's median\_revenue is good or bad compared to other products. So, for our final task, let's examine how this differs to clothing products. We will re-use footwear, adding a filter afterward to count the number of products and median revenue of products that are not in footwear.

```
